Paper Narrative: Calibrated Early Exit (toy example)

internal check before submission · status 2026-01-15

Evidence: L literature · T deduction (proof) · N numerical (this study) State: N in hand and checked · N weaker than the sentence needs · N planned or absent Heavy boxes are the main claims.

In one breath: Early exit saves compute, but its accuracy cost is unclear and unexplained; one **calibrated exit head** removes **38% of the compute with no significant accuracy loss**, the saving is **predicted by the exit rate**, and so existing classifiers can be served about a third cheaper without retraining.

THIN	SUPPORTED	SUPPORTED	THIN	OPEN
"Nobody says when" rests on an unfinished search.	Both halves of the sentence have solid support.	Both numbers measured, 5 seeds, best vs best.	"Disappears when miscalibrated" rests on one seed.	"Without retraining" has no evidence of its own.

To close, in order of damage to the story (at most 4)

1. Run the frozen-backbone experiment, or cut "without retraining" from the payoff.
2. Repeat the calibration ablation with 5 seeds.
3. Finish the prior-work search on the remaining two venues; read the closest paper in full.

Scope of the claims

Two image benchmarks; one GPU type; batch size 1. "No significant loss" is not equivalence: no equivalence test was run.
